Macroscopy Comment:

UNFORMED STOOL:

An UNFORMED stool specimen classified as Type 5 or 6 on the Bristol Stool Chart suggests rapid colonic transit, leading to inadequate water reabsorption and a looser stool consistency. This may result from mild digestive disturbances, dietary changes (such as high fibre or fat intake), stress, or gut microbiota imbalances (dysbiosis). Type 6, in particular, may indicate early-stage diarrhea, commonly linked to irritable bowel syndrome with Diarrhea (IBS-D), food intolerances (e.g., lactose, gluten, FODMAPs), gastrointestinal infections, or inflammatory responses. Clinical recommendations include identifying dietary triggers, ensuring adequate but not excessive fibre intake, and considering probiotic therapy (especially strains like Lactobacillus and Bifidobacterium) to help restore microbial balance. Persistent symptoms may warrant further evaluation for malabsorption syndromes (e.g., celiac disease, pancreatic insufficiency), small intestinal bacterial overgrowth (SIBO), or inflammatory markers to assess for underlying pathology.

FAECAL OCCULT BLOOD NEGATIVE:

Faecal occult blood has not been detected in this specimen. If the test result is negative and clinical symptoms persist, additional follow-up testing using other clinical methods is recommended.

GIT Markers Comment:

beta-GLUCORONIDASE NORMAL:

B-Glucuronidase is considered normal and is within reference range.

ACCREDITATION SCOPE: Please note that the above test is currently not under the laboratory's scope of accreditation.

PANCREATIC ELASTASE NORMAL (>200 ug/g):

A faecal pancreatic elastase level >200 ug/g indicates normal exocrine pancreatic function.

CALPROTECTIN LOW POSITIVE (101-250 ug/g):

A low positive faecal calprotectin level (101–250 ug/g) suggests the presence of gastrointestinal inflammation, though not specific to IBD.

This degree of elevation may be associated with a spectrum of conditions, including mild IBD, gastroenteritis, neoplasia, or medication-related mucosal inflammation (notably from NSAIDs or PPIs). While it does not confirm a diagnosis of IBD, this result warrants further clinical evaluation, particularly if accompanied by persistent gastrointestinal symptoms.

Follow-up testing and/or referral to a gastroenterologist is recommended.

FAECAL TRANSGLUTAMINASE IgA: Negative

Tissue Transglutaminase is the most specific test for Coeliac Disease. Levels less than 100 are considered NEGATIVE.

Treatment:

No treatment required. However, If there is clinical suspicion of Coeliac disease consider testing serum Coeliac markers. Also assess IgG/IgA Food sensitivity tests to identify specific food intolerances.

ACCREDITATION SCOPE: Please note that the above test is currently not under the laboratory's scope of accreditation.

HELICOBACTER PYLORI ANTIGEN: POSITIVE

A POSITIVE result, indicates a current infection and is not affected by the presence of other organisms, antacids, barium sulphate, blood or fat. Please correlate infection clinically with signs and symptoms.

Lab ID Patient ID PAT-100009 **Ext ID** 25283-0010

Test Patient

Sex: Female • 45yrs • 01-Jan-80 123 Home Street, Test Suburb Vic 3125 RECEIVED 10-Oct-25

Treatment:

Triple therapy: PPI, clarithromycin and amoxicillin or metronidazole, 7-14 days.

If penicillin allergic: PPI, clarithromycin and clindamycin or metronidazole, 7-14 days.

A suggested follow up test is recommended within 4 weeks post therapy.

If treatment is unsuccessful, further investigation of H. pylori may be warranted using metagenomic sequencing to evaluate virulence factors and potential resistance gene markers.

M2-PYRUVATE KINASE NEGATIVE:

Negative M2-PK values should be correlated with carcinoembryonic antigen (CEA) markers. M2-PK has a lower sensitivity and specificity in diagnosing pancreatic cancer compared to CA 19-9. However, in patients with adenocarcinoma there is a simultaneous increase of M2-PK and CA 19-9.

ACCREDITATION SCOPE: Please note that the above test is currently not under the laboratory's scope of accreditation.

Microorganism Summary:

AEROMONAS SPECIES DETECTED by PCR

DNA consistent with the presence of Aeromonas species has been detected using PCR techniques.

Aeromonas have been implicated as a cause of both acute and persistent diarrhoeal illness (usually watery) and may be accompanied by fever and/or abdominal pain. Aeromonas is widely distributed in the freshwater, esturaine and marine environments and infection usually occurs in the summer months.

TREATMENT SUGGESTIONS:

Most cases of Aeromonas-associated diarrhoea are self-limited and can be managed with supportive therapy. If treatment is considered necessary, Aeromonas spp. are usually sensitive to Trimethoprim-Sulphamethoxazole and Fluoroquinolones. Sensitivity to tetracycline is variable.

Rule out allergy to above medication before prescribing/taking. Consult ID specialist if patient is showing severe symptoms or immunocompromised.

CRYPTOSPORIDIUM SPECIES DETECTED by PCR

DNA consistent with the presence of Cryptosporidium species has been detected using PCR techniques.

Cryptosporidium infection is thought to occur by environmentally resistant oocysts, zoonotic transmission, nosocomial transmission and direct person-to-person contact. Contamination of public water supply has been associated with outbreaks. Raw foods such as unpasteurized milk and raw meat can also harbor the organism. Cryptosporidium can cause an asymptomatic infection, a mild diarrhoeal illness, or severe enteritis. Symptoms may also include abdominal pain, malaise, nausea and fever.

TREATMENT SUGGESTIONS:

Cryptosporidiosis is generally self-limiting in immunocompetent patients, lasting approximately 2 weeks. In severe cases or immunocompromised treatment options include:

Nitoxanamide 500 mg (child 1 to 3 years: 100 mg; 4 to 11 years: 200 mg) orally, 12 hourly for 3 days

Rule out allergy to above medication before prescribing/taking. Consult ID specialist if patient is showing severe symptoms or immunocompromised.

PLEASE NOTE:

Cryptosporidium detection has been confirmed through a secondary PCR test.

This organism may be classified as a notifiable pathogen. Confirmation has been performed through repeat testing and/or verification on a secondary platform, where required. The result will be reported to the relevant Department of Health in accordance with statutory requirements. For specific state-based notification obligations, please refer to your local public health authority.

Lab ID Patient ID PAT-100009 **Ext ID** 25283-0010

Test Patient

Sex: Female • 45yrs • 01-Jan-80 123 Home Street, Test Suburb Vic 3125 RECEIVED 10-Oct-25

DIENTAMOEBA FRAGILIS DETECTED by PCR.

DNA consistent with the presence of Dientamoeba fragilis has been detected using PCR techniques.

Dientamoeba fragilis appears to be extremely common and may have a cosmopolitan distribution, although there are large variations in prevalence. Dientamoeba fragilis has been linked to intestinal symptoms, especially in children. The most common symptoms associated with this organism are abdominal pain, intermittent diarrhoea, bloating and anorexia.

TREATMENT SUGGESTIONS:

Mild symptoms are self-limiting.

If treatment is warranted, metronidazole for 10 days or a single 2g dose of Tinidazole may be used. Tetracycline has also proven effective in adults.

Rule out allergy to above medication before prescribing/taking. Consult ID specialist if patient is showing severe symptoms or immunocompromised.

AEROMONAS SPECIES: PHYLUM: Proteobacteria

Aeromonas species are Gram-negative bacteria belonging to the phylum Proteobacteria. While primarily found in aquatic environments, some Aeromonas species are transient or opportunistic members of the human gut microbiome. In healthy individuals, their presence is generally low, but in immunocompromised hosts or those with gut dysbiosis, species such as A. hydrophila and A. caviae can cause gastrointestinal infections, leading to symptoms like diarrhea and abdominal pain (Janda and Abbott, 2010). Aeromonas species are also notable for their ability to acquire and disseminate antimicrobial resistance genes, posing a risk in environments with frequent antibiotic use (Pablos et al., 2010). Although their exact role in the gut microbiome is not fully understood, monitoring these bacteria is crucial in assessing their impact on microbial diversity and potential for opportunistic infections.

CITROBACTER FREUNDII COMPLEX: PHYLUM: Proteobacteria

Citrobacter freundii complex consists of several species including C. freundii, C. braakii, C. gillenii, C. murliniae, C. sedlakii, C. werkmanii and C. youngae and are Gram-negative bacteria from the phylum Proteobacteria and is a common resident of the human gut microbiome. Typically found as a commensal organism, C. freundii plays a minor role in maintaining microbial diversity within the gut. However, it is also an opportunistic pathogen, particularly in immunocompromised individuals, and has been linked to infections such as urinary tract infections, pneumonia, and bacteremia (Whalen et al., 2007). In the context of gut health, C. freundii generally poses little risk, but during episodes of dysbiosis or antibiotic treatment, its population can increase, leading to potential infections. Its ability to acquire antibiotic resistance, especially through horizontal gene transfer, makes it a clinical concern when overgrowth occurs. Monitoring C. freundii in gut microbiome studies is essential for understanding its role in both health and disease.

ENTEROCOCCUS FAECALIS: PHYLUM: Firmicutes

Enterococcus faecalis is a Gram-positive bacterium from the phylum Firmicutes and is a common inhabitant of the human gut microbiome. As a commensal organism, it plays a role in maintaining gut homeostasis and contributes to microbial diversity. However, E. faecalis is also an opportunistic pathogen, particularly in immunocompromised individuals or when gut dysbiosis occurs. It has been associated with serious infections such as bacteremia, endocarditis, urinary tract infections, and intra-abdominal infections (Arias and Murray, 2012). A major concern with E. faecalis is its ability to acquire antibiotic resistance, including resistance to vancomycin, making it a significant pathogen in healthcare settings. Although it is normally part of a healthy gut microbiome, monitoring its levels is important to prevent infection outbreaks, particularly in vulnerable populations.

ENTEROCOCCUS FAECIUM: PHYLUM: Firmicutes

Enterococcus faecium is a Gram-positive bacterium from the phylum Firmicutes and is commonly found in the human gut microbiome. While it generally functions as a commensal organism, contributing to microbial diversity and gut homeostasis, E. faecium is also a significant opportunistic pathogen. It is known for causing infections such as bacteremia, endocarditis, and urinary tract infections, particularly in immunocompromised individuals or during gut dysbiosis (Arias and Murray, 2012). A major concern with E. faecium is its high level of antibiotic resistance, especially to vancomycin, which has made it a major healthcare-associated pathogen. Its ability to acquire and

 Lab ID

 Patient ID
 PAT-100009

Test Patient

Sex: Female • 45yrs • 01-Jan-80 123 Home Street, Test Suburb Vic 3125 RECEIVED 10-Oct-25

transfer resistance genes elevates its clinical importance. While it plays a normal role in the gut microbiome, monitoring its levels is critical for preventing healthcare-related infections.

KLEBSIELLA OXYTOCA: PHYLUM: Proteobacteria

Klebsiella oxytoca is a Gram-negative bacterium from the phylum Proteobacteria and is part of the human gut microbiome, typically present in low abundance as a commensal organism. It contributes to the microbial diversity of the gut but can become an opportunistic pathogen, particularly in immunocompromised individuals or during gut dysbiosis. K. oxytoca has been associated with antibiotic-associated hemorrhagic colitis, a form of colitis characterized by mucosal damage and bleeding (Hofmann et al., 2020). Beyond the gut, K. oxytoca is linked to hospital-acquired infections, such as pneumonia, urinary tract infections, and septicemia. Its potential for antibiotic resistance, including resistance to beta-lactam antibiotics, raises concerns in clinical settings. Monitoring K. oxytoca in the gut is important for understanding its role in health, disease, and antibiotic resistance dynamics.

PSEUDOMONAS AERUGINOSA: PHYLUM: Proteobacteria

Pseudomonas aeruginosa is a Gram-negative bacterium commonly known for its opportunistic pathogenicity. While it is primarily associated with infections in immunocompromised patients and chronic infections such as cystic fibrosis, its presence in the gut microbiome is less well-characterized. In the gut, P. aeruginosa can be part of the microbial community, often as a transient or minor member. Its potential impact on gut health includes interactions with other gut microbiota, which could influence inflammation and microbial balance (Pang et al., 2019). Despite its role as a pathogen, understanding its dynamics within the gut microbiome could offer insights into its broader ecological roles and impact on gastrointestinal health (Kresse et al., 2018).

STREPTOCOCCUS AGALACTIAE: Phylum: Firmicutes

Streptococcus agalactiae is a Gram-positive bacterium commonly found in the human gut microbiome. It is part of the group known as beta-hemolytic streptococci. While S. agalactiae is predominantly recognized for its role as a pathogen causing infections in neonates, pregnant women, and immunocompromised individuals, it is also a normal component of the gut microbiota. Within the gut, S. agalactiae may influence microbial diversity and contribute to the overall balance of the gut flora. Its presence in the gut microbiome is linked to potential impacts on gut health and immune responses, though its pathogenic potential under certain conditions is well-documented (Schrag et al., 2002; Kline et al., 2011).

CANDIDA KRUSEI: PHYLUM: Ascomycota

Candida krusei is a yeast belonging to the phylum Ascomycota and is found as part of the human gut microbiome. Unlike more common Candida species, C. krusei is intrinsically resistant to fluconazole, a widely used antifungal, which makes it a significant concern in clinical settings (Pfaller and Diekema, 2007). While generally present in low abundance in the gut, it can act as an opportunistic pathogen, particularly in immunocompromised individuals or those undergoing prolonged antibiotic or antifungal treatments. In the gut microbiome, C. krusei is usually commensal, but when gut dysbiosis occurs, such as during illness or antibiotic use, it may proliferate and contribute to infections like candidiasis (Papon et al., 2013). Monitoring its levels is critical, especially in hospital environments, to prevent and manage potential gut-related infections.

CANDIDA PARAPSILOSIS: PHYLUM: Ascomycota

Candida parapsilosis is a yeast from the phylum Ascomycota and is a part of the human gut microbiome. Typically found in low abundance, it can act as a commensal organism but has the potential to become opportunistic, particularly in immunocompromised individuals or those undergoing gut dysbiosis (Tavanti et al., 2005). C. parapsilosis is often associated with invasive infections, such as fungemia, especially in hospital settings, where it can cause catheter-related bloodstream infections. In the gut microbiome, its role is generally minor, but its ability to form biofilms and resist certain antifungal agents makes it a concern when overgrowth occurs. Monitoring C. parapsilosis levels in the gut is important for understanding its potential contribution to infection, particularly in vulnerable populations.

BIFIDOBACTERIUM BIFIDUM LOW:

Lab ID Patient ID PAT-100009 **Ext ID** 25283-0010

Test Patient

Sex: Female • 45yrs • 01-Jan-80 123 Home Street, Test Suburb Vic 3125 RECEIVED 10-Oct-25

Bifidobacterium bifidum is a Gram-positive bacterium belonging to the phylum Actinobacteria and is one of the earliest colonizers of the human gut, particularly in infants. It plays a key role in maintaining gut health by breaking down complex carbohydrates, including human milk oligosaccharides, in infants, and promoting the production of short-chain fatty acids, which support gut barrier function and immune modulation (O'Callaghan and van Sinderen, 2016). In the adult gut microbiome, B. bifidum continues to contribute to microbial balance, inhibiting pathogenic bacteria and supporting a healthy immune response. It has been associated with various health benefits, including improved digestion and protection against gastrointestinal infections. Its probiotic potential makes it a focus in therapeutic interventions for gut health (Rivière et al., 2014). Monitoring B. bifidum in gut microbiome studies provides insights into its essential role in maintaining a healthy microbiota.

BIFIDOBACTERIUM BREVE:

Bifidobacterium breve is a Gram-positive bacterium within the phylum Actinobacteria, commonly found in the gut microbiome of infants and adults. It is a key player in early gut colonization, particularly in breastfed infants, where it helps digest human milk oligosaccharides and supports the development of the immune system (Turroni et al., 2012). In the adult gut, B. breve contributes to the fermentation of complex carbohydrates, producing short-chain fatty acids such as butyrate, which promote gut health by enhancing the intestinal barrier and reducing inflammation (Rivière et al., 2014). Its probiotic properties have been associated with various health benefits, including improved digestion, protection against pathogens, and potential roles in managing conditions such as irritable bowel syndrome (IBS). Monitoring B. breve levels can provide insights into its role in maintaining a healthy gut microbiome.

BIFIDOBACTERIUM LONGUM LOW:

Bifidobacterium longum is a Gram-positive bacterium from the phylum Actinobacteria and is a prominent member of the human gut microbiome. Found in both infants and adults, B. longum plays a crucial role in fermenting complex carbohydrates, including dietary fibers and human milk oligosaccharides, to produce short-chain fatty acids, such as acetate and lactate, that promote gut health (O'Callaghan and van Sinderen, 2016). This species is associated with several health benefits, including enhancing gut barrier function, modulating the immune system, and protecting against gastrointestinal pathogens. Its probiotic properties make it a key component in many probiotic supplements aimed at improving digestion and alleviating symptoms of disorders like irritable bowel syndrome (Rivière et al., 2014). Monitoring B. longum in gut microbiome studies helps assess its contribution to microbial balance and overall health.

BIFIDOBACTERIUM PSEUDOCATENULATUM LOW:

Bifidobacterium pseudocatenulatum is a Gram-positive bacterium belonging to the phylum Actinobacteria and is a common member of the human gut microbiome. It is particularly abundant in infants but persists into adulthood, contributing to gut health by fermenting dietary fibers and producing short-chain fatty acids such as acetate, which support intestinal barrier function and reduce inflammation (Rivière et al., 2014). Recent studies have shown that B. pseudocatenulatum has potential probiotic properties, including modulating immune responses and inhibiting the growth of harmful pathogens in the gut (O'Callaghan and van Sinderen, 2016). Its role in gut microbiota is associated with maintaining microbial diversity and promoting a balanced gut environment, making it a promising candidate for therapeutic interventions aimed at improving gut health and managing gastrointestinal disorders.

ESCHERICHIA COLI:

Escherichia coli (E. coli) is a Gram-negative bacterium belonging to the phylum Proteobacteria and is a key component of the human gut microbiome. Most strains of E. coli are commensal, contributing to normal gut functions such as vitamin K production and preventing colonization by pathogenic bacteria. It plays a crucial role in maintaining gut homeostasis and microbial diversity (Tenaillon et al., 2010). However, certain strains of E. coli can become pathogenic, leading to gastrointestinal diseases such as diarrhea, urinary tract infections, and more severe conditions like hemolytic uremic syndrome. Pathogenic strains, such as enterohemorrhagic E. coli (EHEC), can produce toxins like Shiga toxin, which can cause serious infections (Kaper et al., 2004). While most E. coli strains are beneficial, monitoring its pathogenic variants is important for maintaining gut health.

LACTOBACILLUS ACIDOPHILUS LOW:

Lactobacillus acidophilus is a Gram-positive bacterium belonging to the phylum Firmicutes and is a prominent member of the human gut microbiome. Known for its probiotic properties, L. acidophilus plays a crucial role in maintaining gut health by producing lactic acid, which

 Lab ID

 Patient ID
 PAT-100009

lowers the pH in the intestines and inhibits the growth of harmful bacteria (Rousseaux et al., 2007). It also aids in digestion, supports immune modulation, and enhances the gut barrier's integrity. L. acidophilus is commonly found in the small intestine and is frequently used in probiotic supplements to promote a healthy microbiome, especially after antibiotic use. It has been studied for its potential in treating conditions like irritable bowel syndrome, diarrhea, and inflammatory bowel disease, highlighting its importance in gut health and microbial balance (Seth et al., 2018) .

LACTOBACILLUS PLANTARUM LOW:

Lactobacillus plantarum is a Gram-positive bacterium from the phylum Firmicutes, prominently present in the human gut microbiome. Known for its probiotic properties, L. plantarum contributes to gut health by fermenting dietary fibers into lactic acid, which lowers intestinal pH and inhibits the growth of harmful microorganisms (Hammes & Hertel, 2009). This species is also involved in maintaining the integrity of the gut barrier and modulating immune responses, which can help prevent or alleviate gastrointestinal disorders such as irritable bowel syndrome (IBS) and inflammatory bowel disease (IBD) (O'Callaghan & van Sinderen, 2016). Its ability to adhere to the gut lining and produce antimicrobial peptides makes L. plantarum a valuable component of a healthy gut microbiota.

Parasites/Worms Comment

ASCARIS SPECIES (Roundworm) DETECTED:

Ascaris species (including A. lumbricoides and A. suum) are the most common parasitic roundworm in humans. Hosts may be asymptomatic, causing only malnutrition and growth retardation or present with severe gastrointestinal (abdominal pain, nausea, vomiting, bloating or diarrhoea) or lung symptoms (fever, cough or wheezing). Adult worms can also migrate causing cholecystitis, cholangitis, pancreatitis, small bowel obstruction or appendicitis. Infection occurs via ingestion of eggs, usually found in stool-contaminated soil.

TREATMENT SUGGESTIONS:

Effective treatments include Albendazole or Mebendazole single oral dose. Rule out allergy to above medication before prescribing/taking. Can repeat dose after 4-6 weeks. Whole family to be treated simultaneously. Hand hygiene and washing bedding /clothes in hot water cycle is recommended to prevent recurrence. A repeat test should be suggested post therapy.

Methodology

Automated Chemistry/Immunochemistry, Chemiluminescence Immunoassay (CLIA), Enzyme-Linked Immunosorbent Assay (ELISA), Gas Chromatography-MS (GC/MS), Microscopy, Fluorescence Enzyme Immunoassay (FEIA), pH Electrode, MALDI-TOF (Matrix-Assisted Laser Desorption/Ionization Time of Flight), Polymerase Chain Reaction (PCR), Quantitative PCR (qPCR)
